CommonSpot™ 8.0.2 Release Notes

Paper|Thin

.

About this Document

This document summarizes the following for this service pack:

- Important Notes

- Enhancements

- Notable Bug Fixes

For detailed instructions for installing CommonSpot, see the *Installation Guide* appropriate for the release you are currently using.

For detailed instructions on upgrading from a previous version of CommonSpot, see the appropriate release of the *CommonSpot Upgrade Guide*.

Important Notes

Read All Relevant Release Notes

If you are upgrading from a version earlier than 8.0.1, please read the release notes *for all interim versions*, specifically, for updates to browser, JDK and ADF support. These release notes document changes between 8.0.1 and 8.0.2 *only.*

Schema Update

You must run a schema update as part of the 8.0.2 update. Although this service pack contains no schema changes, updates to CommonSpot "factory" data require a database schema update.

CCAPI Authentication

This release adds a check for licensed contributors before allowing CCAPI use.

Enhancements

This release includes the following improvements to CommonSpot:

Server Migration

This release includes an enhancement that enables refreshing a development server with production data, where the production server had a ROPS and the development server did not. Information for the ROPS configuration, is now transferred smoothly to the development environment.

User Profiles

You can now allow or prohibit users to edit their own profiles through a new Enable User Profile Editing option available through Customer Admin – General Security. Upgrading to CommonSpot 8.0.2 *does not* automatically grant this permission; this permission *is granted* (to all authenticated users) when a new customer is added or with a "clean-slate" install. Administrators who want all users to be able to edit their own permissions should grant this permission to Authenticated Users.

Notable Bug Fixes

This service pack fixes issues with:

Admin

The Rename a Subsite option was visible to contributors who did not have Subsite Admin rights.

Custom Elements

- Global Custom Element permissions did not always take into consideration Element instance security, sometimes preventing non-admin users/groups from searching for more records to add when manually selecting records to render. Also corrected a JavaScript init() error.

- Internal errors sometimes occurred with render mode set to manual selection when editing a Custom Element.

- Custom Elements that used the RTE on multiple tabs didn't save text when switching tabs in the editor.

- Text fields with certain characters (quotes" ", ampersands &, or open or close delimiters <>) in Custom Element data rendered incorrectly after certain events, such as link updates.

Custom Modules

The attribute scope for override-cfmail.cfm was missing CC, REPLYTO, and BCC.

Debugging

In some configurations, running in Adobe ColdFusion debug mode displayed an "attribute is undefined" error on every page (rendering was not affected).

Delete/Copy/Move

- A change to the 'Include In' checkboxes for page metadata was not honored during a Page Move operation.

- When moving a template to another subsite, CommonSpot appended '(template)' to the name, resulting in an invalid character error for the template name. Templates are now saved as 'name-template'.

Integrated Support

The "error output" field did not accept HTML content.

Link References

- Updates to registered URLs containing a query string did not propagate to referring pages with links to that Registered URL.

- Users with insufficient permission could change referring links on a page through the Page Tools menu.

Page Index Elements

A white background color, instead of no color, was displayed for page indexes if no class was specified.

Rich Text Editor

- You could not select an existing RTE image in Chrome.

- Hyperlinks remained in Image Properties after removal via the DOM menu.

Security

Some sites with a large number of subsites reported a brief performance degradation after content permissions were updated at the subsite level.

Style Sheets, Style Sheet Sets

After breaking template inheritance, the Style Sheet path name for the page displayed an invalid path name.

Tabular Layout Element

Layout cells did not take on the assigned background color. This release removes the Font Properties fields from the layout dialog if the page has styles enabled.

User/Group Management

- When deleting a user, the "summary of user's contributions" link did not work for users whose names included an apostrophe.

- After changing the expiration date for a user account, re-opening the date picker displayed the current date as the default. The calendar now opens to the previously assigned expiration date.
